## 1. Introduction

In finite dimension it is well known that, for any Poisson manifold, its cotangent bundle can be provided with a natural structure of Lie algebroid. On the other hand the same is true for prolongation of a Lie algebroid. For an adaptation for such results in the Banach setting, we propose the notion partial Poisson structure on a Banach manifold M, which is defined by an anchor on a weak subbundle  $T^{\flat}M$  of  $T^*M$ . In this context, we obtain only a "partial structure of Banach-Lie algebroid" on  $T^{\flat}M$  and not a

Banach-Lie algebroid, even if  $T^{\flat}M = T^*M$ .

## 1. Introduction

In finite dimension it is well known that, for any Poisson manifold, its cotangent bundle can be provided with a natural structure of Lie algebroid. On the other hand the same is true for prolongation of a Lie algebroid. For an adaptation for such results in the Banach setting, we propose the notion partial Poisson structure on a Banach manifold M, which is defined by an anchor on a weak subbundle  $T^{\flat}M$  of  $T^*M$ . In this context, we obtain only a

"partial structure of Banach-Lie algebroid" on  $T^{\flat}M$  and not a Banach-Lie algebroid, even if  $T^{\flat}M = T^*M$ .

Although the prolongation of a Banach Lie algebroid is naturally provided with an anchor, when the typical fiber of the Lie algebroid is not finite dimensional, the Lie bracket gives rise only to a "partial Banach-Lie algebroid structure" on this prolongation.

2. Problems about gene-

1. Weak symplectic. On a Banach manifold M, any symplectic form  $\omega$  on M is such that the morphism  $\omega^{\flat} : X \mapsto \omega(., X)$  is not surjective in general and so  $\omega$  is weak symplectic form. 2. Locality of a bracket. In the finite dimensional setting, we have bump functions and so for any x in M, any germ of function at x can be extended to a global one. If we consider a Banach manifold M which has bump functions the same is true.

On a Banach manifold M, any symplectic form  $\omega$  on M is such that the morphism  $\omega^{\flat}: X \mapsto \omega(., X)$  is not surjective in general and so  $\omega$  is weak symplectic form. 2. Locality of a bracket. In the finite dimensional setting, we have bump functions and so for any x in M, any germ of function at xcan be extended to a global one. If we consider a Banach manifold M which has bump functions the same is true. But many interesting geometrical or physical examples of Banach manifolds do not satisfy such assumption. Thus a Poisson Lie bracket defined on global smooth functions can be not defined on local ones. So, it seems natural to assume that a Poisson bracket must be defined on smooth functions over open set in M .

2. Problems about gene4. Module of local sections. In finite dimension, we can define an almost Lie Bracket  $[.,.]_P$  on the cotangent bundle, in term of Lie derivative. The Jacobi identity for a Lie Poisson bracket and the fact that the set of sections of  $T^*M_{|U}$  is a finite dimensional module generated by  $\{df, f \in C^{\infty}(U)\}$  imply that the bracket  $[.,.]_P$  satisfies the Jacobi identity. Unfortunately this no longer true in Banach setting.

 $\mathfrak{u}^v(x,a) = (x,a,0,\mathfrak{u}(x)).$ 

In finite dimension, TA can be provided with a canonical Lie bracket induced by the Lie bracket on A. Unfortunately this result is no more true in infinite dimensional Banach setting. Note that since each vertical section of TA is a vertical vector field, the usual Lie bracket of vector field gives rises to a Lie bracket for sections of VAand we get a natural structure on Lie algebroid on VA.
